

# On the practical cost of Grover for AES key recovery

Sarah D. UK NCSC

### **Quantum Computing and Cryptography**

- Shor's algorithm period finding
  - Clear threat to public key algorithms.
  - New post-quantum algorithms recently standardised by NIST.
  - Protocol adaptation underway in IETF and elsewhere.
- Grover's algorithm unstructured search problem Possible limited threat to symmetric key algorithms.
- Where should mitigation efforts be focused?

#### Aims

- Assess impact of Grover on symmetric cryptography for near-term quantum hardware.
  - AES considered here, analysis similar for other symmetric algorithms.
- Estimate logical implementation and parallelisation overheads on any hardware. ightarrowLogical qubit-cycles.
- Estimate error correction overheads when using planar surface code. ightarrowSurface code cycles and physical qubit count.

### **Unstructured Search Problem**

- For a set X with |X| = N and a function  $f: X \to \{0, 1\}$ , find unique  $x \in X$  such that ulletf(x) = 1
- Unstructured means that we cannot do better than brute force, i.e. repeatedly ightarrowevaluating f on values in X.
- Expected number of queries to f on a classical computer is therefore  $\frac{N}{2}$

### **Unstructured Search Problem – Relation to Cryptography**

- Can set up the key recovery problem for a symmetric block cipher (e.g. AES-128) as an unstructured search problem.
- Given ciphertext C = Enc(K, P) for some unknown key K and some cribbed (guessed) plaintext P.
- Let X be the set of all possible key values and define  $f: X \to \{0,1\}$ :  $f(x) = \begin{cases} 1 & \text{if } \text{Enc}(x, P) = C, \\ 0 & \text{otherwise.} \end{cases}$

### **Grover's Algorithm**

- Published by Lov Grover in 1996. ightarrow
- Solves the unstructured search problem with  $O(\sqrt{N})$  quantum queries to the ightarroworacle function f.
- Asymptotically optimal for this problem (Zalka, 1997) ightarrow

### **Grover's Algorithm - Initialisation**

#### Start with evenly distributed amplitudes in superposition:

### **Grover's Algorithm – Oracle Function**

#### Flip the sign of the exceptional value:

$$\frac{1}{\sqrt{N}} \sum_{x} |x\rangle \quad \xrightarrow{U_f} \quad \frac{1}{\sqrt{N}} \sum_{x} (-1)^{f(x)} |x\rangle$$

### **Grover's Algorithm – Iteration and Measurement**

- <u>Iterate oracle and reflection operators  $O(\sqrt{N})$  times and finally measure to</u> ightarrowrecover desired state  $\omega$  with high probability.
- Oracle queries are made sequentially.
- Terminating early (e.g. making only  $\frac{N}{s}$  queries) reduces success probability by a igodotfactor  $S^2$ .

### Grover's Algorithm – Implications for Cryptography

- Can apply Grover to AES with key length k bits ( $k \in \{128, 192, 256\}$ ). ullet
- Succeeds with high probability after  $(\pi/4)\sqrt{2^k}$  quantum AES queries. ightarrow
- For AES-128, Grover takes around 2<sup>64</sup> quantum AES queries compared • with 2<sup>127</sup> classical queries for brute force exhaustion.
- This is sometimes reported as "Grover's halves the effective key length of ightarrowsymmetric algorithms."

### Grover's Algorithm – Implications for Cryptography

- However, the square-root speed-up headline neglects significant details: ightarrow
  - The cost of quantum AES implementations. ullet
  - The fact that the AES queries must be sequential. ullet
  - The overheads from quantum error correction. ullet

### **Oracle Implementation**

- Depth the number of sequential quantum gates that must be executed.
- Width the maximal number of qubits needed during execution.

Depth

### **Oracle implementation**

- Different implementations optimise for different metrics. ullet
- We use Jang et al. "Quantum analysis of AES", IACR ePrint 2022/683:
  - Minimises (circuit depth)<sup>2</sup> x (number of qubits). ullet

AES Key Size	Depth	Qubits	Depth <sup>2</sup> x Qubits
128	731	3428	2 <sup>30.8</sup>
192	874	3748	2 <sup>31.4</sup>
256	1025	4036	2 <sup>32.0</sup>

### Maximum depth

Max donth	Cycle time			
	1µs	200ns	1ns	
240	12.7 days	2.55 days	18.3 mins	
2 <sup>48</sup>	8.92 years	1.78 years	3.26 days	
2 <sup>56</sup>	2,280 years	457 years	2.28 years	
264	585,000 years	117,000 years	585 years	

### Parallelisation

- Limiting maximum depth limits number of iterations that can be performed. ightarrow
- Reducing number of iterations by a factor of S reduces success probability by  $S^2$ . ightarrow
- Alternatively, we can split the search space into subsets of size  $N/S^{2}$ . ightarrow
- Either way,  $S^2$  quantum processors are needed to cover the same search space. ightarrow
- Overall costs (compute cost x time taken) have increased by a factor of S. ightarrow

### **Costing Methodology – When Parallelisation Is Required**

- 1. Calculate number of AES iterations per run from the implementation depth and MAX DEPTH choice.  $N_{iter} = \frac{D_{max}}{D_{AEC}}$
- 2. Calculate the number of quantum processors needed, i.e. find S such that.  $N_{iter} = \left(\frac{\pi}{4}\right) \frac{2^{k/2}}{\sqrt{s}}$
- 3. Calculate the total number of logical qubits required.  $W_{tot} = SW_{AES}$
- 4. Calculate the cost in terms of number of logical qubit cycle  $C_{tot} = W_{tot} D_{max} = SW_{AES} D_{max} = \left(\frac{4}{2^{k/2}\pi} N_{iter}\right)^{-2}$

es.  

$$W_{AES}D_{max} = \left[2^k \left(\frac{\pi}{4}\right)^2 \frac{D_{AES}^2 W_{AES}}{D_{max}}\right]$$

#### **Quantum error correction**

- Important to distinguish between perfect logical qubits and noisy physical qubits.
- Logical qubits are built from many physical qubits using quantum error correction.
- The planar surface code is currently the best studied QEC scheme.
  - Exponentially suppresses errors as code distance *d* increase.
  - Uses  $2d^2 1$  physical qubits to produce one logical qubit.

#### **Quantum error correction**

Figure 1: A surface code qubit with d = 5

- Measurement Qubit

#### **Quantum error correction**

- All error correction schemes have quantum gates that cannot be applied directly. ullet
- These can instead be applied by producing "magic states", which can be ightarrowcombined with basic gates to produce the desired non-basic gate.
- Creating high accuracy magic states will be done via magic state distillation, ightarrowwhich creates them by combining many lower accuracy states.
- Magic state distillation requires additional quantum hardware, known as magic ulletstate factories or distilleries.

#### AES-128 surface code costs

	10 <sup>-4</sup> physical error		10 <sup>-6</sup> physical error	
Maximum depth	Physical qubits	Surface code cycles	Physical qubits	Surface code cycles
2 <sup>40</sup>	2 <sup>97.1</sup>	2 <sup>128.7</sup>	2 <sup>91.6</sup>	<b>2</b> <sup>125.0</sup>
2 <sup>48</sup>	2 <sup>81.7</sup>	2 <sup>120.9</sup>	2 <sup>76.7</sup>	2 <sup>117.4</sup>
2 <sup>56</sup>	2 <sup>66.3</sup>	2 <sup>112.8</sup>	<b>2</b> <sup>62.9</sup>	<b>2</b> <sup>111.5</sup>
<b>2</b> <sup>64</sup>	2 <sup>51.1</sup>	2 <sup>105.3</sup>	2 <sup>48.1</sup>	2 <sup>104.2</sup>

#### **AES-128 overheads**

•	Logical implementation:	31 bits	
•	Parallelisation:	8 - 32 bits	(de
•	Error correction:	6 - 10 bits	(de
	Distillation:	1 - 3 bits	(inc

#### These are not entirely independent: less parallelisation needs more error correction.

- pending on maximum depth)
- pending on physical error rate)
- cluded in error correction overhead)

#### **Potential cost reductions**

- Smaller AES implementations. ullet
- Faster cycle times. ightarrow
- Better physical error rates. ightarrow
- More efficient error correcting codes. ullet

### Conclusions

- The practical security impact of Grover with existing techniques on plausible ulletnear-term quantum hardware is limited.
  - Bounding the length of time an adversary is prepared to wait introduces unavoidable overheads from parallelisation.
  - Error correction adds further overheads, but these are less significant.
  - Early post-quantum migration efforts should focus on traditional public-key algorithms.
